Chapter 3: How to Review the Literature and Develop Research Questions

Lecture Notes

The purpose of Chapter Three is to help you to learn how to come up with a research topic, refine it, and get ready to write your research proposal which is discussed in Chapter 4.

Sources of Research Ideas

Research ideas and research problems originate from many sources. We discuss four of these sources in the text: everyday life, practical issues, past research, and theory. Regardless of the source of your idea, a key point is that you must develop a questioning and inquisitive approach to life when you are trying to come up with research ideas.

- **Everyday life** is one common source of research ideas.

  Based on a questioning and inquisitive approach, you can draw from your experiences and come up with many research topics. For example, think about what educational techniques or practices you believe work well, or do not work well. Would you be interested in doing a research study on one or more of those techniques or practices?

- **Practical issues** can be a source of research ideas.

  What are some current problems facing education (e.g., facing administrators, teachers, students, parents). What research topics do you think can address some of these current problems?

- **Past research** can be an excellent source of research ideas.

  In my opinion (BJ), past research is probably the most important source of research ideas. That’s because a great deal of educational research has already been conducted on a multitude of topics, and, importantly, research usually generates more questions than it answers. This is also the best way to come up with a specific idea that will fit into and extend the research literature. For students planning on writing a thesis or dissertation, the use of past research is extremely helpful, and remember to not just look at the variables and the results, but also carefully examine how they conducted the study (i.e., examine the methods).

  When you read a research article, it will be helpful for you to think about the ideas shown in Table 3.1.
Theory (i.e., explanations of phenomena) can be a source of research ideas.

- Can you summarize and integrate a set of past studies into a theory?
- Are there any theoretical predictions needing empirical testing?
- Do you have any "theories" that you believe have merit? Test them!
- If there is little or no theory in the area of interest to you, then think about collecting data to help you generate a theory using the grounded theory technique.

**Ideas that Can't Be Researched Empirically**

The point in this section is that empirical research (i.e., research that is based on the collection of observable data) cannot provide answers to “ultimate,” “metaphysical,” or “ethical” questions. If a question is asking which value is true or correct, empirical research can’t offer the solution. For example, is school prayer good? Should homosexuals be allowed to legally marry? Should the teaching of Christianity (and no other religion) be provided in public schools? These are moral and legal issues which cannot be directly addressed or resolved by empirical research in the social or behavioral sciences. John
Dewey made the point that empirical research can provide answers about how to get to valued endpoints, but he took the valued endpoints for granted (e.g., democracy, equality, education for all). So do not expect to conduct an empirical research study that will "show whether school prayer should be adopted."

**Review of the Literature**

After you have identified your research idea, and identified a general problem that sounds interesting to you, the next step is to become familiar with the published information on your topic. Conducting a literature review will help you to see if your topic has already been researched, help you to see how you might need to revise your research idea, and show methodological techniques and problems specific to your research problem that will help you in designing a study. Most importantly, after conducting a thorough literature review, your specific research questions and hypotheses will become clearer to you.

A literature review can take a different form in qualitative and quantitative research:

- **In qualitative research** (which often means exploratory research), little prior literature may be available. Furthermore, too much review may make a researcher "myopic." Literature is especially important during the later stages (e.g., interpreting results, discussion) of exploratory research. Still, for much qualitative research, we recommend that a literature review is conducted to see what has been done and to provide sensitizing concepts. Then when data are collected, the researcher can use strategies (discussed in chapter 10) to minimize the researcher’s biases.

- **In quantitative research**, the researcher directly "builds" on past research. Therefore, review of prior research must be done before conducting the study. In quantitative research, the literature review will help you to see if your research problem has already been done, show you data collection instruments that have been used, show designs that have been used, and show theoretical and methodological issues that have arisen.

**Sources of Information**

There are several major sources of information for you to use when conducting a literature review.

- **Books** is a good starting point. It gives you an overview and a summary of relevant research and theory.
• **Journals** is another excellent source. Journals provide more recent information than books and provide full length empirical research articles for you to carefully examine.

• **Computer databases** are excellent sources for locating information. The most important computer database in education is ERIC. Other important databases are PsycINFO or PsycLIT (for psychological research), SocioFILE and Sociological Abstracts (for sociological research), and Dissertation Abstracts (for summaries of doctoral dissertations in education and related fields). We strongly recommend that you do **not** limit your search to a single computer database. Also, we strongly recommend that you **do not search only for full-text articles** because this will eliminate most of the best published research.

**Conducting the Literature Search**

In this section, we have included some practical material on conducting the literature search.

- We have included a Table (3.2) that shows how to search ERIC. You should access ERIC through your library to get the full version.

- But remember: **Do not limit your searching to ERIC; use multiple data bases!**

- In Table 3.4 we explain how to evaluate the **quality** of Internet resources. It is important for you to understand that the quality of material on the Internet varies widely and it must be evaluated before use.

- Using the Public Internet. The Internet has obviously become extremely important. Below in Table 3.3 is a list of some useful subject directories, search engines, and meta-search engines that is from your chapter:
Feasibility of the Study

Before deciding whether to carry out your research project, you must decide whether it would be feasible to conduct. You should do this as early as possible so you don’t waste your time. This means that you must design a research study that can be carried out given your available resources (e.g., time, money, people). Interviewing all children with ADHD in your state probably would not be feasible for a single research study. Interviewing a set of children with ADHD at your school would be more feasible. Furthermore, part of determining feasibility involves making sure that the study can be carried out ethically. The Institutional Review Board will help you with this decision.

So far we have discussed how to come up with your research topic and how to find the needed information.
As seen in the following figure (Figure 3.1 from your book), after you get your topic, you need to move to determining your research problem, your statement of the purpose of your study, your statement of the research questions, and if you are conducting a quantitative study you will also state need to your hypotheses. Note that movement from the top to the bottom of Figure 3.1 involves a movement from the general to the specific (e.g., a hypothesis is much more specific than a research topic). Also note that as you move from the top to the bottom, you will need to conduct your literature review so that you can determine what specific research questions and/or hypotheses need to be addressed. In fact, it is usually helpful (when conducting basic or applied research) to start your literature review right at the beginning of the process shown in Figure 3.1.

**FIGURE 3.1 Flowchart of the development of a research idea**

---

**Statement of the Research Problem**

As seen in the above figure, the research problem is the educational issue or problem within your broad topic area. In other words, you start with your topic
and then try to identify one or more research problems that you believe need to be solved in that topic area.

- In quantitative research, research problems tend to emphasize the need to explain, predict, or describe something.

- In qualitative research, research problems tend to focus on exploring a process, an event, or a phenomenon.

- Mixed research is based on both or a mixture of the above.

  **Statement of the Purpose of the Study**

As seen in the figure, your research purpose follows from the problem you have selected, and it is your statement of your intent or objective for your research study. It is important to include this in your proposals and final reports because it helps orient your reader to your study.

- In quantitative research, the purpose identifies the specific type of relationship being investigated using a specific set of variables.

- In qualitative research, the purpose focuses on exploring or understanding a phenomenon.

- In mixed research, the purpose might focus on conducting a study that explores, generates, and tests and confirms relationships or ideas

  **Statement of Research Questions**

After you have completed your literature review and have digested the literature, you will need to make an exact statement of the specific research questions you want to pursue. This will help ensure that you have a good grasp of what you want to do, it will enable you to communicate your idea to others, and it will help guide the research process (e.g., what variables will be examined, what methods will be needed). A good literature review will logically end with your specific research questions.

- In quantitative research, a research question typically asks about a relationship that may exist between or among two or more variables. It should identify the variables being investigated and specify the type of relationship (descriptive, predictive, or causal) to be investigated. For example: What effect does playing football have on students’ overall grade point average during the football season?
We have included scripts for writing quantitative research questions in Table 3.5.

- In qualitative research, a research question asks about the specific process, issue, or phenomenon to be explored or described. For example: What are the social and cultural characteristics of a highly successful school where students and teachers get along well and students work hard and achieve highly? Here is another research question: How does the social context of a school influence perservice teachers’ beliefs about teaching? Here is another: What is the experience of a teacher being a student like?

- In mixed research, research question(s) might ask about relationships, process, and contextual interactions that might exist, such as “What works for whom in different contexts?”

Formulating Hypotheses

- If you are conducting a quantitative research study, you will typically state your specific hypotheses that you have developed from your literature review. A hypothesis is the researcher’s prediction of the relationship that exists among the variables being investigated.

- If you wrote a research question, the hypothesis will be your tentative answer to your question. For the quantitative research question stated above (i.e., What effect does playing football have on students’ overall grade point average during the football season?) the related hypothesis might go like this: Students who play football during the football season will experience a decrease in their GPAs as compared to students not playing football.

- Unlike in quantitative research (where hypotheses are stated before collecting the data), hypotheses in qualitative research are often generated as the data are collected and as the researcher gains insight into what is being studied.

- In mixed research studies you might formally state a hypothesis to be tested via the quantitative (and possibly the qualitative) part of the mixed study. Hypotheses sometimes can be generated during a mixed study and then followed with testing in the same overall research study.
Consumer Use of the Literature

Frequently there will be no need to conduct an empirical research study because the necessary research will have already been done. In other words, many times, only a literature review will be needed to answer your questions.

- We have provided checklist for evaluating research studies in Tables 3.6, 3.7, and 3.8. These will help you to evaluate each study you review.

Don’t forget this point that we want to continue to emphasize: never place too much confidence in a single research study. That is, you should place much more confidence in a research finding that has been replicated (i.e., shown in many different research studies).

- Because of the importance of viewing the full set of studies on an issue and the built-in benefit of replication when this is done, you can see why we recommend that you pay special attention to meta-analyses when you find them in your literature searches.

- A meta-analysis is a quantitative technique for summarizing the results of multiple studies on a specific topic. It will tell you if a variable consistently has been shown to have an effect as well as the average size of effect.
